(54) **Tubing hanger with annulus valve**

(57) A subsea wellhead apparatus includes a subsea wellhead housing 10 installed at the ocean floor, a casing hanger 12 connectable to the to the upper end of a casing string and supported in the bore of the housing to suspend the casing string in the well bore, and a tubing hanger 13 connectable to the upper end of a tubing string and also supported within the housing bore above the casing hanger for suspending the tubing string within the casing string. A primary valve 42 and a secondary emergency valve 54 are installed in series for controlling a passageway in the tubing hanger which connects the annulus between the casing and tubing strings with the bore of the housing above the tubing hanger and thus with an additional passageway in a Christmas tree which is installed on the head above the tubing hanger.

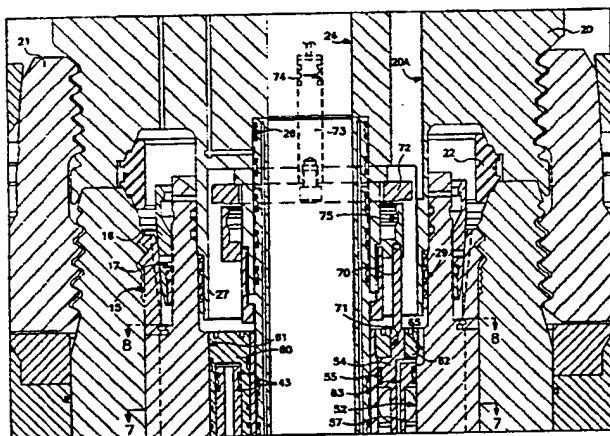

FIG. 1

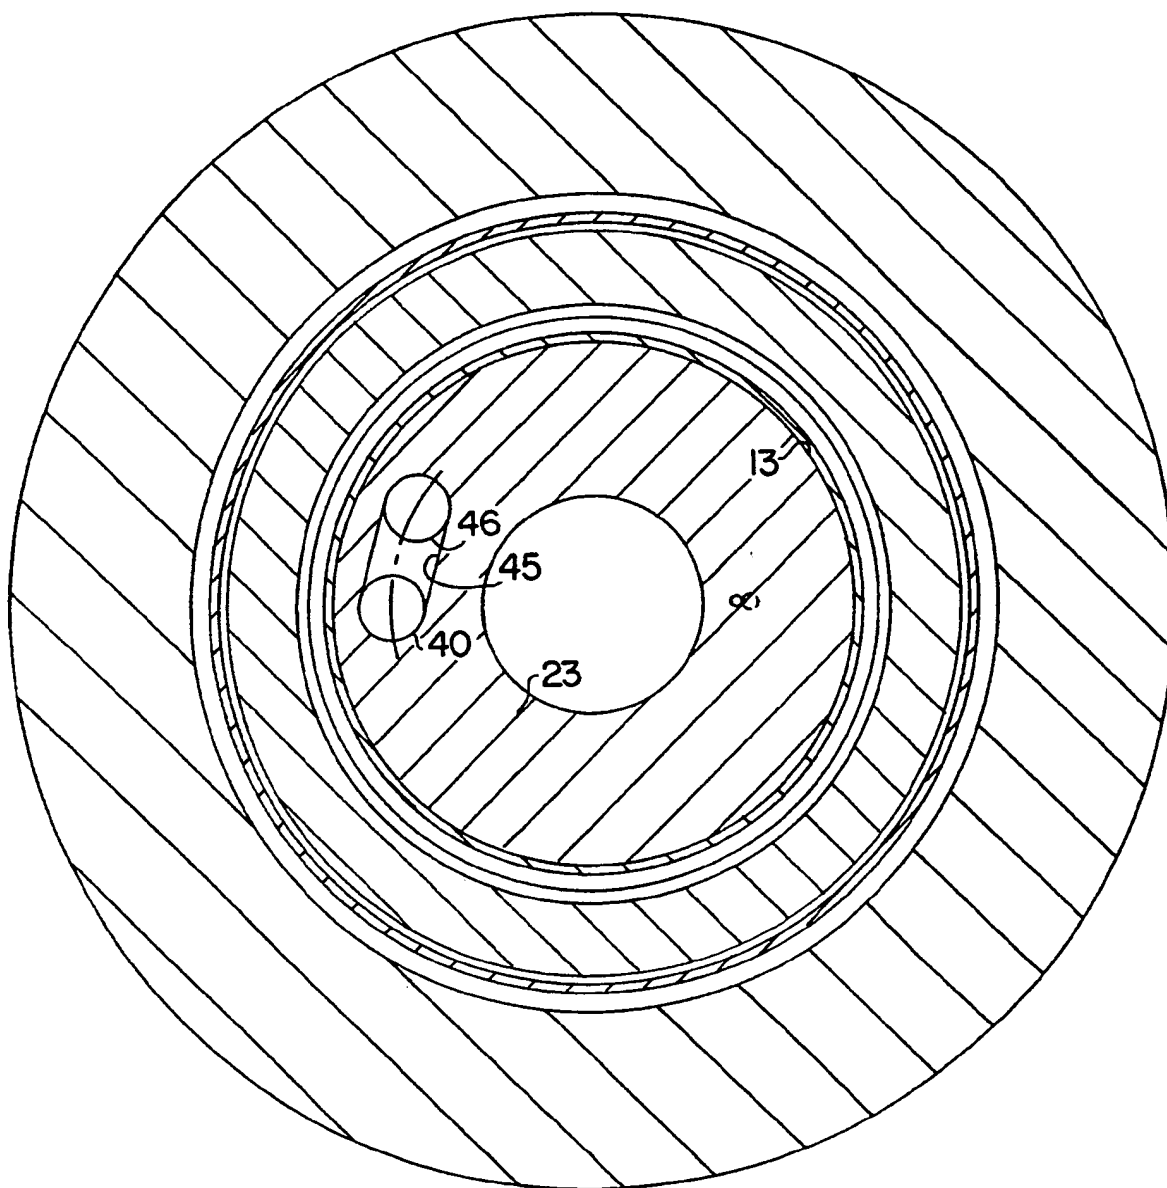

FIG. 5

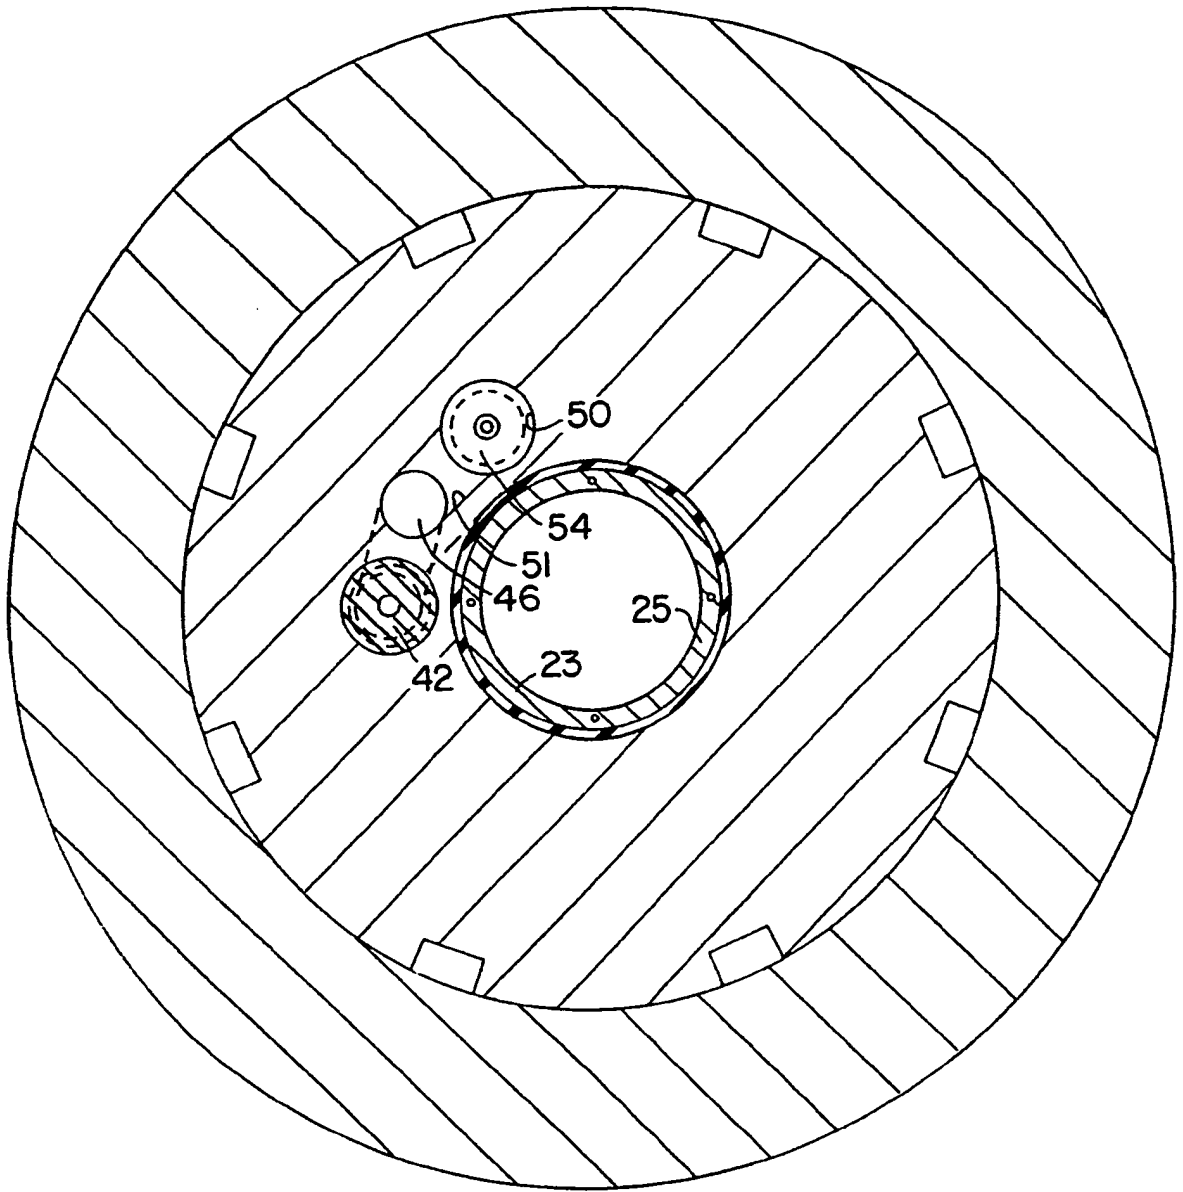

FIG. 6

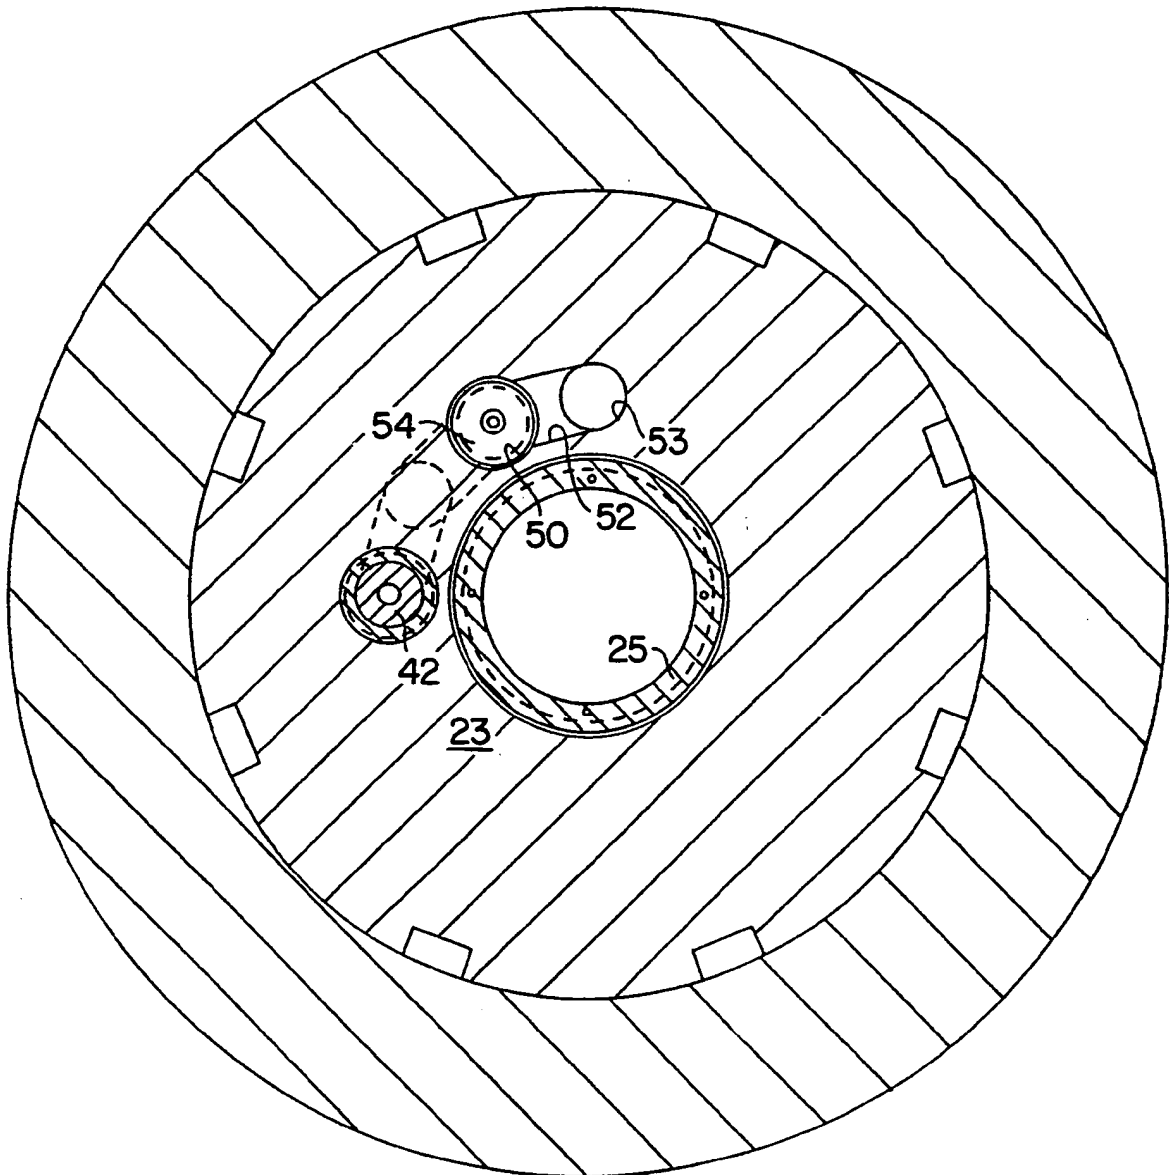

FIG. 7

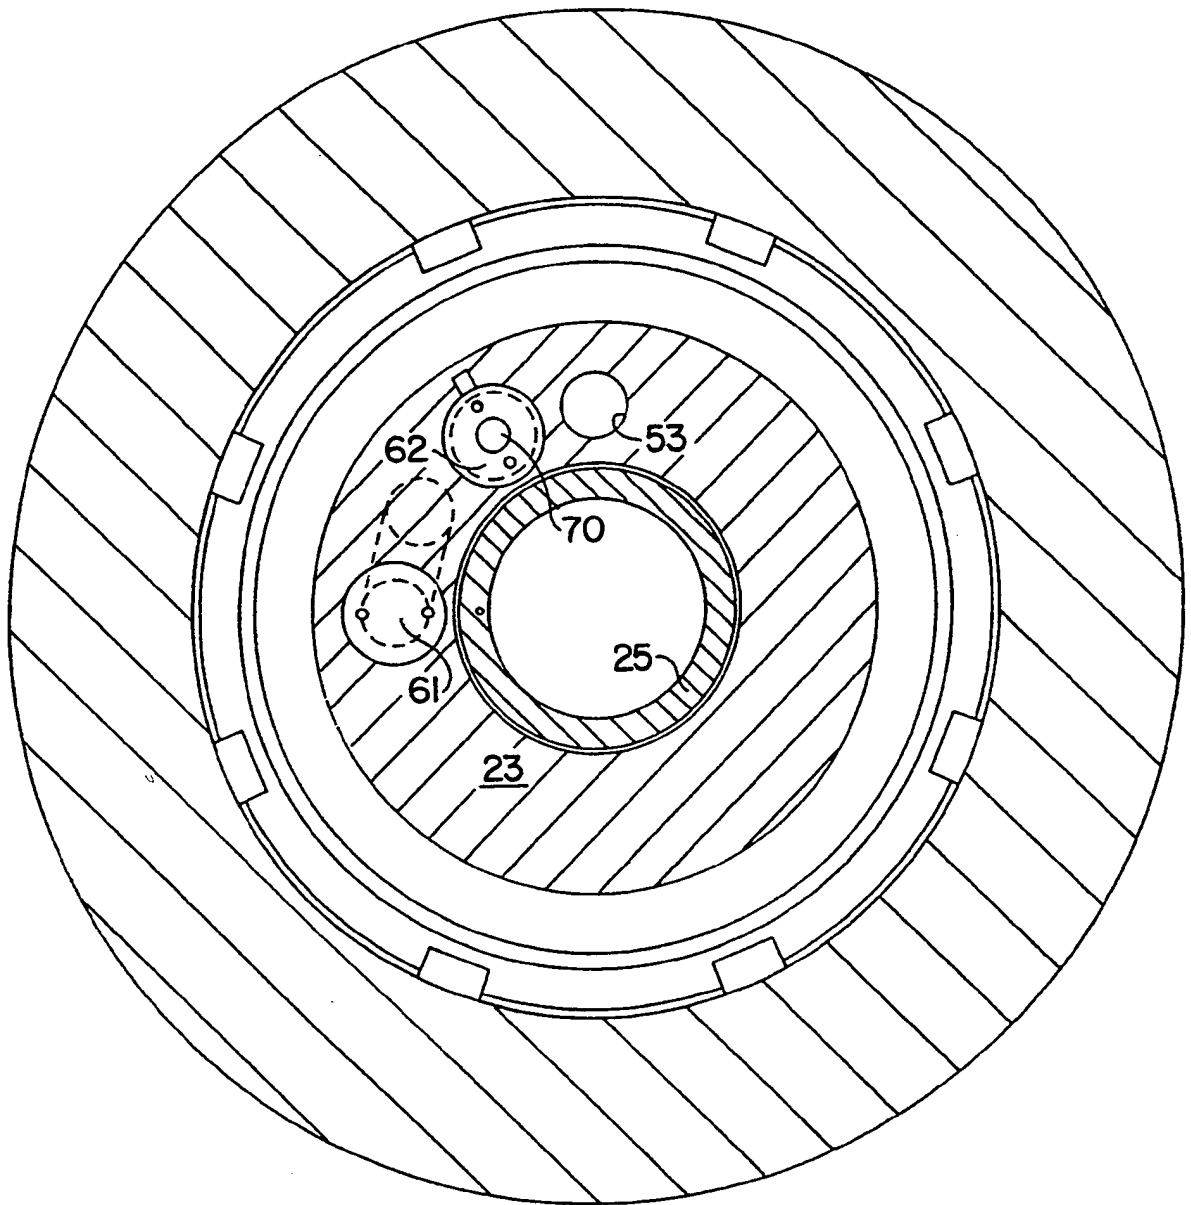

FIG. 8

SUBSEA WELLHEAD APPARATUS

This invention relates generally to subsea wellhead apparatus which includes, among other things, a subsea wellhead housing installed at the ocean floor, a casing hanger connectable to the upper end of a casing string and supported in the bore of the housing to suspend the casing string in the well bore, and a tubing hanger connectable to the upper end of a tubing string and also supported within the housing bore above the casing hanger for suspending the tubing string within the casing string. More particularly, it relates to improvements in such apparatus which includes valve controlled passageway means in the tubing hanger which connects the annulus between the casing and tubing strings with the bore of the housing above the tubing hanger and thus with additional passageway means in a Christmas tree which is installed on the head above the tubing hanger.

During the completion of an offshore well, the casing and tubing hangers are lowered into supported positions within the wellhead housing through a blowout preventer (BOP) stack installed above the housing. Following completion of the well, the BOP stack is replaced by a Christmas tree having suitable valves for controlling the production of well fluids. The casing hanger is sealed off with respect to the housing bore and the tubing hanger is sealed off with respect to the casing hanger or the housing bore, so as to effectively form a fluid barrier between the annulus between the casing and tubing strings and the bore of the housing above the tubing hanger. However, during completion of the well as well as following completion of

the well, there may be reasons to communicate between the annulus and Christmas tree and thus permit fluid circulation between them. Hence, it has been proposed to provide the tubing hanger with valves (known as "annulus valves") for controlling flow through passageway means in the tubing hanger connecting the annulus and bore, whereby the passageway means may be closed and well fluid contained at least during those intervals in which the BOP stack or Christmas tree is removed.

Commonly owned U.S. Patent 5,143,158 relates to wellhead equipment _____ including a tubing hanger having an annulus valve which is an improvement in many respects over prior valves of this general type. Like any other valve, however, this annulus valve is susceptible of failure for various reasons, such as malfunction of the operating system for shifting the valve member between alternate positions, leakage of one or more seal rings, etc. The inability to close such a valve in this particular environment could be catastrophic because there is no way to repair or replace it without removing the tree and penetrating the tubing hanger to obtain access to it, all of which would result in loss of the fluid pressure barrier across the hanger. Hence, it is an object of this invention to provide wellhead equipment which is so constructed and arranged as to overcome this and other problems with prior equipment and valves of this type, and, more particularly, which provides a means by which flow through the passageway means may be easily and quickly shut off in such emergency situations without having to penetrate the tubing hanger.

In the preferred and illustrated embodiment there is provided a subsea wellhead, which includes a wellhead housing, a _____

casing hanger, and a tubing hanger supported within the bore of the housing as above described, together with a Christmas tree removably mounted on the housing above the upper end of the tubing hanger and having second passageway means forming a continuation of the upper end of the passageway means in the tubing hanger, to connect with the annulus between the suspended casing and tubing strings beneath the tubing hanger with the bore of the housing above the tubing hanger. As in prior apparatus of this type, a primary valve having a valve member is installed in the first passageway means and has means thereon which is responsive to a remote source of fluid pressure for selectively moving said first valve member between opened and closed position. This valve may, but is not necessarily, be made in accordance with the aforementioned Patent No. 5,143,158. A second, emergency valve _____ including a second valve member is also installed in the first passageway means in series with the first valve member and has means for moving said second valve member from a normally open to a closed position independently of operation of the first valve member, whereby, the first passageway means may be closed in an emergency situation in which the first described valve malfunctions, and the tree replaced by BOP stock so that necessary repairs may be made. Preferably the means for so moving the second valve member includes means which is responsive to a second remote source of fluid under pressure.

In the illustrated and preferred embodiment, the tubing hanger has an elongate cavity with a _____ side inlet from and a side outlet to the first passageway means, and the second valve member includes a spool which is sealably shiftable longitudinally within the cavity

between open and closed positions respectively connecting and disconnecting the inlet and outlet. More particularly, the spool has a hole through it to balance forces across it due to fluid pressure on its opposite ends.

5 Still further, the second valve member has a stem extending through one end of the cavity, and a piston is reciprocable in a cylinder in the Christmas tree for receiving fluid pressure from the above mentioned remote source of pressure fluid to urge it against the stem and
10 thus move second valve member to closed position. More particularly, the stem has means thereon which may be grasped from above the tubing hanger in order to move the second valve member back to open position.

15 In the drawings, wherein like reference characters are used throughout to designate like parts:

 Figs. 1 and 2 are vertical sectional views of respectively upper and lower portions of a subsea wellhead constructed in accordance with the present invention, and showing the valve member of the first or main valve as well
20 as the valve member of the second or emergency shutoff valve in their open positions to permit flow through the passageway means in the tubing hanger connecting the annulus between the casing and tubing strings with the upper end of the tubing hanger and thus with additional
25 passageway means in the Christmas tree installed on the wellhead above the tubing hanger;

 Figs. 3 and 4 are similar views of the upper and lower portions, respectively, of the wellhead apparatus Figs. 1 and 2, but with the pistons in the tree shown in a
30 rotationally oriented position and lowered to move the valve member of the emergency shutoff valve to its position closing the passageway means through the tubing hanger;

 Fig. 5 is a cross-sectional view of a lower portion of

the tubing hanger, as seen along broken lines 5-5 of Fig. 2, and showing the lowermost passageway section connecting the lower end of the tubing hanger with the lower end of the cavity in which the valve member of the primary valve reciprocates, and a lateral port connecting the lowermost section with a vertical passageway section intermediate the valve members;

Fig. 6 is another cross-sectional view of an intermediate portion of the tubing hanger, as seen along broken lines 6-6 of Fig. 2, and showing the upper end of the intermediate section of the passageway means connected by a lateral port to an inlet to the cavity in the tubing hanger in which the valve member of the second or emergency shutoff valve reciprocates;

Fig. 7 is still another cross-sectional view of the tubing hanger, as seen along broken lines 7-7 of Fig. 1, and showing an outlet from the upper end of the cavity for the secondary valve connecting with a lateral port leading to an upper section of the passageway means in the tubing hanger connecting with its upper end; and

Fig. 8 is a still further cross-sectional view of the tubing hanger, as seen along broken lines 8-8 of Fig. 1, and showing plugs closing the upper ends of the cavities for the first and second valve members as well as the upper end of the upper section of the passageway means at its intersection with a cylindrical recess in the upper end of the hanger in which a lower extension of the Christmas tree is received.

With reference now to the details of the above-described drawings, the overall wellhead equipment includes a wellhead housing 10 adapted to be installed in an upright position on the ocean floor and having a bore 11 therethrough connected to the upper end of an outermost

casing string (not shown) to form an upward continuation of the well bore and string. A casing hanger 12 is installed within the bore of the housing to suspend an inner casing string (not shown) within the outer string, and an annular space between the outside of the casing hanger and the bore 5 11 of the wellhead housing is closed off by a seal assembly 12A which may be removably installed and locked in the position shown in any suitable manner, as in the manner shown and described in Patent No. 4,757,860, also assigned 10 to the assigned of the present application.

A tubing hanger 13 is also installed in the bore of the wellhead housing and supported on the upper end of the casing hanger to suspend a tubing string 14 therefrom within the inner casing string. The annular space between 15 the tubing hanger and a bore through the casing hanger is closed off by a seal assembly 13A similar to the assembly 12A, and the tubing hanger is held down in supported position by a lock ring 15 held in locking engagement with grooves about the bore of the housing by a wedge 16, 20 installed in a wedge-shaped space between the inside of the lock ring and a tubular extension 17 on the upper end of the tubing hanger.

A Christmas tree 20 is installed on the upper end of the wellhead housing 10 and secured thereto by a lock ring 25 21 of a suitable connector, such as that shown and described in Patent No. 4,497,172, also assigned to the assignee of the present application. As described in such patent, the lock ring is adapted to be wedged radially inwardly in order to preload the flexible lips of a seal 30 ring 22 into sealing engagement with the inner tapered surfaces at the upper end of the wellhead housing bore and the lower end of the Christmas tree.

The tubing hanger has a bore 23 therethrough which

forms an upward continuation of the tubing string 14, and the Christmas tree has a central bore 24 therethrough forming an upward continuation of the bore through the tubing hanger. These bores are connected by an
5 intermediate sleeve 25 which is received in enlarged portions of the upper end of the bore through the tubing hanger and the lower end of the bore through the Christmas tree. This sleeve has several passages for connecting ports in the hanger as well as in the tree to pass fluid
10 under pressure to and from suitable locations in the wellhead, all in a manner well known in the art.

The outer diameter of downwardly extending tubular extension 26 forming the enlarged portion of the bore through the Christmas tree extends closely into the upper
15 tubular extension 17 of the tubing hanger. An annular recess 27 extends upwardly from the lower end of the lower tubular extension of the tree, and a seal assembly 29 similar to those above described is disposed between the tubular extensions at the upper end of the tubing hanger
20 and lower end of the Christmas tree. Thus, this seal assembly cooperates with the seal assemblies 12A and 13A to form a fluid barrier across the bore of the wellhead housing.

As shown and described in connection with the annulus
25 valve of the aforementioned Patent No. 5,143,158, the passageway means through the tubing hanger includes a lowermost passageway section 40 extending upwardly from the lower end of the tubing hanger and leading to the lower end of an elongate cavity 41 formed in the tubing hanger in
30 axial alignment therewith. A valve member 42 is received in the cavity for vertical reciprocation between an upper position, as shown in Figs. 1A and 1B, wherein seal rings about its lower end are above a side port 45 connecting the

lowermost passageway section with an intermediate vertical section 46 extending parallel thereto, as shown in Figs. 5 and 6, and a lower position (not shown) in which seal rings on its lower end enter the upper end of section 40 below port 45 to close the connection between the lower passageway section and the side port, thus closing the passageway means through the tubing hanger.

As described in the aforementioned Patent No. 5,143,158, the elongate valve member 42 is adapted to be reciprocated between its opened and closed positions by pressure fluid from a remote source, as for example, on or about the Christmas tree. For this purpose, the valve member has an intermediate piston 42A sealably reciprocal within an enlarged annular chamber 41A about the cavity, and carries seal rings 43 and 44 about its upper and lower ends for sealably sliding within the upper and lower portions of the cavity above and below the annular chamber. Seal rings 43 and 44 remain within the cavity in both the opened and closed positions of the valve, while, as above described, the lowermost seals 46 about the valve member move from positions above the side port in the open position of the valve to positions below the side port in the closed position thereof so that the seal rings 44 and 46 bridge the side port and thus close the passageway means. Fluid pressure may be supplied to or exhausted from opposite sides of the piston within the chamber through ports connecting with a suitable remote source, as explained in the above noted patent.

The secondary emergency shutoff valve also includes an elongate vertical cavity 50 extending parallel to the first or main shutoff valve, but oriented rotationally with respect thereto. As shown in Fig. 6, the upper end of the passageway section 46A shown in Fig. 5 is connected to a

lower intermediate portion of the cavity 50 by means of a side port 51 (see Fig. 6) to provide an inlet thereto. The upper portion of the cavity is in turn connected through a lateral port 52 to provide an outlet therefrom connecting
5 with an upward section 53 of the passageway means which connects at the upper end with the upward end of the tubing hanger within the recess surrounded by its upper tubular extension, as shown in Fig. 8.

As shown in the drawings, the second valve includes a
10 valve member 54 comprising a spool having a pair of vertically spaced rings 55 and 56 sealably reciprocable in the cavity 50 and connected by a stem 57. In the upper position of the valve member, shown in Figs 1 and 2, the upper ring 55 is above the side port 52, and the lower ring
15 is below the lower side port 51, thus forming a connection between lateral ports 51 and 52 and thus the upper and lower vertical sections of the passageway means. However, upon shifting of the valve member downwardly to the position of Figs. 3 and 4, the upper ring 55 is disposed
20 between the lateral ports 51 and 52, thereby closing the passageway means, as may be desirable upon malfunction of the primary valve upstream of the emergency valve.

The upper end 61 of an enlarged opening about the cavity 41 for the primary valve is closed by a plug 60, so
25 that upon removal of the plug, the valve member 42 may be moved therethrough for repair or replacement. The upper end of the cavity 50 for the second valve is also closed by a plug 62 such that it too may be removed for repair or replacement. The lower side of the plug 62 provides a stop
30 to locate the emergency valve member in its upper open position, as shown in Figs. 1A and 1B.

A hole 63 is formed through the stem 57 and rings 54 and 56 of the emergency valve member to connect at its

lower end with the lower end of the lower ring and at its upper end with a slot 65 formed in the threaded hole to receive plug 62, as shown in Figs. 1, 3 and 8, and thus with the recess in the lower tubular extension 26 of the tree in which an upward extension 20A of the passageway means in the Christmas tree 20 is formed for leading to a suitable flow control system in or connected with the tree. More particularly, the cross-sectional areas of the rings are essentially equal so that the valve member is pressure balanced and normally held in its upper position open by frictional engagement of the pistons with the cavity. The pressure balance of the valve member also permits it to be raised upwardly and returned to its open position with a minimum of force.

A rod 70 extends upwardly from the upper end of the upper piston and guidably through a hole 71 in the plug 62 closing the upper end of the cavity and into the annular recess formed within the lower tubular extension of the tree which leads to passageway section 20A in the tree. The upper end of the rod is thus disposed beneath a ring 72 carried within the recess for connection to the lower ends of pistons 73 sealably reciprocal within cylinders 74 formed in the lower end of the recess in the Christmas tree. Thus, upon lowering of the pistons from the upper position shown in broken lines in Fig. 1A to the lower position shown in Fig. 2A, the ring engages and lowers the rod 70, and thus the valve member, downwardly to its closed position.

The ring is bolted to the lower ends of the pistons, and a groove 75 is formed about its inner diameter for access by any suitable tool to permit the emergency valve to be raised to its open position. Like the malfunctioning primary valve member, the second valve member may also be

replaced or repaired.

As previously described, the sources of pressure fluid for opening and closing the primary valve and closing the emergency valve, are independent of one another. Such sources may be in or around the Christmas tree or from an remote operated vehicle adapted to be moved into connection with the blowout preventer or the Christmas tree.

CLAIMS

1. A subsea wellhead, comprising
 - a wellhead housing having a bore therethrough,
 - a tubing hanger supported within the bore of the housing to suspend a tubing string within the well bore, and having first passageway means connecting the annulus between the casing and tubing strings beneath the tubing hanger with its upper end,
 - a Christmas tree removably mounted on the housing above the upper end of the tubing hanger and having second passageway means forming a continuation of the upper end of the first passageway means,
 - a first valve including a first valve member installed in the first passageway means and having means thereon which is responsive to a remote source of fluid pressure for selectively moving said first valve member between opened and closed position, and
 - a second valve including a second valve member installed in the first passageway means in series with the first valve member and having means for moving said second valve member from a normally open to a closed position independently of operation of the first valve member.
2. A wellhead of the character defined in claim 1, wherein,
 - said means for moving the second valve member includes means thereon which is responsive to a second source of fluid under pressure.

3. A wellhead of the character defined in Claim 1 or Claim 2, wherein

the tubing hanger has an elongate cavity with a side inlet from and a side outlet to the first passageway means, and

said second valve member includes a spool sealably shiftable longitudinally within the cavity between open and closed positions respectively connecting and disconnecting the inlet and outlet.

4. A wellhead of the character defined in claim 3, wherein

the spool has a hole therethrough to balance forces due to fluid pressure on its opposite ends.

5. A wellhead of the character defined in Claim 3 or Claim 4, wherein

said second valve member has a stem extending through one end of the cavity, and

a piston is reciprocable in a cylinder in the Christmas tree and adapted to receive fluid pressure from a remote source of pressure fluid to urge it against the stem and thus move the second valve member from open to closed position.

6. A wellhead of the character defined in claim 5, wherein

the stem has means thereon which, upon removal of the Christmas tree, may be grasped from above the tubing hanger in order to move the second valve member back to open position.

7. A tubing hanger for use in a subsea wellhead housing having a bore therethrough and a casing hanger supported within the bore of the housing to suspend a casing string therefrom, comprising

- a tubular body having a bore therethrough and adapted to be landed within the bore of the housing to suspend a tubing string connected to its bore within the casing string and having passageway means which, upon landing of the tubular body, connects the annulus between the casing and tubing strings with the upper end of the tubing hanger and thus with another passageway means in a Christmas tree adapted to be removably mounted on the wellhead housing above the tubing hanger,
 - a first valve including a first valve member installed in the passageway means in the hanger body and having means thereon responsive to a remote source of pressure fluid for selectively moving the first valve member between opened and closed positions, and
 - a second valve including a second valve member installed in the passageway means in the hanger body in series with the first valve member and having means for moving said second valve member from a normally open to a closed position independently of operation of the first valve
8. A tubing hanger of the character defined in claim 7, wherein,
- said means for moving the second valve member includes means thereon which is responsive to a second remote source of fluid under pressure.
9. A tubing hanger of the character defined in Claim 7 or 8, wherein
- said second valve member has means thereon which is accessible, upon removal of the Christmas tree from above the upper end of the tubing hanger, to permit it to be moved from closed to open positions.

10. A tubing hanger of the character defined in Claim 7, 8 or 9, wherein

the tubing hanger body has an elongate cavity with a side inlet from and a side outlet to the passageway means therein, and

said second valve member includes a spool sealably shiftable longitudinally within the cavity between open and closed positions respectively connecting and disconnecting the inlet and outlet.

11. A tubing hanger of the character defined in claim 10, wherein

the spool has a hole therethrough to balance forces due to fluid pressure on its opposite ends.

12. A tubing hanger of the character defined in Claim 10 or 11, wherein

said second valve member has a stem extending through one end of the cavity, in position to be engaged by a piston reciprocable in a cylinder in the Christmas tree to urge it against the stem and thus move second valve member to closed position.

13. A tubing hanger of the character defined in claim 12, wherein

the stem has means thereon which, upon removable of the Christmas tree, may be grasped from above the hanger body in order to move the piston back to open position.

14. A subsea wellhead substantially as hereinbefore described and illustrated in the accompanying drawings.

15. A tubing hanger substantially as hereinbefore described and illustrated in the accompanying drawings.
